### **FIELD OF THE INVENTION**

The present invention is directed to compounds, methods and compositions for the treatment or prevention of viral infections using nucleoside analogues. More specifically, the invention describes N<sup>4</sup>-acyl-substituted cytosine nucleoside analogues, pharmaceutically acceptable salts, prodrugs, or other derivatives thereof, and the use thereof in the treatment of a viral infection, and in particular a human immunodeficiency virus (HIV) or hepatitis B virus (HBV) infection.

### **BACKGROUND OF THE INVENTION**

In 1981, acquired immune deficiency syndrome (AIDS) was identified as a disease that severely compromises the human immune system, and that without exception leads to death. In 1983, the etiological cause of AIDS was determined to be what is now known as human immunodeficiency virus (HIV).

Another virus that causes a serious human health problem is the hepatitis B virus (HBV). HBV is second only to tobacco as a cause of human cancer. The mechanism by which HBV induces cancer is unknown. It is postulated that it may directly trigger tumor development, or indirectly trigger tumor development through chronic inflammation, cirrhosis, and cell regeneration associated with the infection.

After a 2- to 6-month incubation period, during which the host is typically unaware of the infection, HBV infection can lead to acute hepatitis and liver damage, resulting in abdominal pain, jaundice and elevated blood levels of certain enzymes. HBV can cause fulminant hepatitis, a rapidly progressive, often fatal form of the disease in which large sections of the liver are destroyed.

Patients typically recover from the acute phase of HBV infection. In some patients, however, high levels of viral antigen persist in the blood for an extended, or indefinite, period, causing a chronic infection. Chronic infections can lead to chronic persistent hepatitis. Patients infected with chronic persistent HBV are most common in developing countries. By mid-1991, there were approximately 225 million chronic carriers of HBV in Asia alone, and worldwide, almost 300 million carriers. Chronic persistent hepatitis can cause fatigue, cirrhosis of the liver, and hepatocellular carcinoma, a primary liver cancer.

In Western, industrialized countries, the high-risk group for HBV infection includes those in contact with HBV carriers or their blood samples. The epidemiology of HBV is very similar to that of HIV/AIDS, which is a reason why HBV infection is common among patients infected with HIV or suffering from AIDS. However, HBV is more contagious than HIV.

In 1985, it was reported that the synthetic nucleoside 3'-azido-3'-deoxythymidine (AZT) inhibited the replication of HIV. Since then, several other synthetic nucleosides, including but not limited to 2',3'-dideoxyinosine (ddI), 2',3'-dideoxycytidine (ddC), 2',3'-dideoxy-2',3'-didehydrothymidine (d4T), (-)-2',3'-dideoxy-3'-thiacytidine (3TC), and (-)-carbocyclic 2',3'-didehydro-2',3'-dideoxyguanosine (carbovir) and its prodrug abacavir, have proven effective against HIV. After phosphorylation to the 5'-triphosphate by cellular kinases, these synthetic nucleosides are incorporated into a growing strand of viral DNA, causing chain termination, because they lack a 3'-hydroxyl group. Some nucleosides also inhibit the viral enzyme reverse transcriptase.

3TC (lamivudine) and interferon are currently the only FDA-approved drugs for the treatment of HBV infection. Viral resistance develops within 6 months of 3TC treatment in about 14% of patients.

Cis-2-hydroxymethyl-5-(5-fluorocytosin-1-yl)-1,3-oxathiolane (FTC) is currently in clinical trials for the treatment of HIV and separately for HBV by Triangle Pharmaceuticals, Inc. See Schinazi *et al.* (1992) Selective inhibition of human immunodeficiency viruses by racemates and enantiomers of cis-5-fluoro-1-[2-(hydroxymethyl)-1,3-oxathiolane-5-yl]cytosine. *Antimicrob. Agents Chemother.* **36**, 2423-2431; US Pat. Nos. 5,210,085; 5,914,331; 5,814,639; WO 91/11186; and WO 92/14743.

The success of 2',3'-dideoxy- and 2',3'-didehydro-2',3'-dideoxy-nucleosides (referred to as a "ddN" or "d2N" nucleoside and a "d4N" nucleoside, respectively) in inhibiting the replication of HIV *in vivo* or *in vitro* has led a number of researchers to design and test a variety of modified d2- and d4-nucleosides. One modification has been the replacement of the 5-hydrogen on cytosine nucleosides with fluorine, resulting in several 5-fluorocytosine nucleosides with antiviral activity, including but not limited to  $\beta$ -D- and  $\beta$ -L-2',3'-dideoxy-5-fluorocytine ( $\beta$ -D-D2FC and  $\beta$ -L-D2FC) (US Pat. Nos. 4,788,181 and 6,156,737).

$\beta$ -D-2',3'-Dideoxy-2',3'-didehydro-5-fluorocytidine (d4FC) and its use to treat hepatitis B was first described in Example 2 of European Pat. Application No. 0 409 227 A2 (Ajinomoto Co., Inc.). Netherlands Pat. No. 8901258 (Stichting Rega V.Z.W.) discloses generally 5-halogeno-2',3'-dideoxy-2',3'-didehydrocytidine derivatives for use in treating HIV and HBV.  $\beta$ -D- and  $\beta$ -L-2',3'-didehydro-2',3'-dideoxy-5-fluorocytidine were further described in US Pat. Nos. 5,703,058; 5,905,070; 6,232,300; and 5,561,120. US Pat. No. 5,703,058 claims a method for the treatment of HIV and/or HBV infection that includes administering an effective amount of  $\beta$ -L-d4FC in combination or alternation with cis-2-hydroxymethyl-5-(5-fluorocytosin-1-yl)-1,3-oxathiolane, cis-2-hydroxymethyl-5-(cytosin-1-yl)-1,3-oxathiolane, 9-[4-(hydroxymethyl)-2-cyclopenten-1-yl]-guanine (carbovir), 9-[(2-hydroxyethoxy)methyl]-guanine (acyclovir), interferon, 3'-deoxy-3'-azido-thymidine (AZT), 2',3'-dideoxyinosine (ddI), 2',3'-dideoxycytidine (ddC), (-)-2'-fluoro-5-methyl- $\beta$ -L-ara-uridine (L-FMAU) or 2',3'-didehydro-2',3'-dideoxythymidine (d4T). US Pat. No. 5,905,070 claims a method for the treatment of HIV and HBV infection that includes administering an effective amount of  $\beta$ -D-d4FC in combination or alternation with cis-2-hydroxymethyl-5-(5-fluorocytosin-1-yl)-1,3-oxathiolane, cis-2-hydroxymethyl-5-(cytosin-1-yl)-1,3-oxathiolane, 9-[4-(hydroxy-methyl)-2-cyclopenten-1-yl]-guanine (carbovir), 9-[(2-hydroxyethoxy)methyl]guanine (acyclovir), interferon, 3'-deoxy-3'-azido-thymidine (AZT), 2',3'-dideoxyinosine (ddI), 2',3'-dideoxycytidine (ddC), (-)-2'-fluoro-5-methyl- $\beta$ -L-ara-uridine (L-FMAU) or 2',3'-didehydro-2',3'-dideoxythymidine (d4T). US Pat. No. 6,232,300 claims a method to treat HIV with  $\beta$ -D-d4FC.

Modification of the amino group of antiviral cytosine nucleosides has not been fully explored. Only a few N<sup>4</sup>-substituted cytosine 2',3'-dideoxy nucleosides and N<sup>4</sup>-substituted cytosine 2',3'-didehydro-2',3'-dideoxy nucleosides have been reported. These

include N<sup>4</sup>-benzoyl-2',3'-didehydro-2',3'-dideoxycytidine (Kawaguchi *et al.*, Studies on 2',3'-dideoxy-2',3'-didehydropyrimidine nucleosides. II. N<sup>4</sup>-benzoyl-2',3'-dideoxy-2',3'-didehydrocytidine as a prodrug of 2',3'-dideoxy-2',3'-didehydrocytidine (DDCN), Chem. Pharm. Bull. (1989), 37(9), 2547-9), N<sup>4</sup>-benzoyl-2',3'-dideoxycytidine (Gulbis *et al.* (1993) Structure of a dideoxynucleoside active against the HIV (AIDS) virus. Acta Cryst. C49, 1095-1097), N<sup>4</sup>-acetyl-2',3'-didehydro-2',3'-dideoxy-5-fluorocytidine, and N<sup>4</sup>-isopropyl-2',3'-didehydro-2',3'-dideoxy-5-fluorocytidine (Shi *et al.* (1999)) Synthesis and biological evaluation of 2',3'-didehydro-2',3'-dideoxy-5-fluorocytidine (d4FC) analogues: discovery of carbocyclic nucleoside triphosphates with potent inhibitory activity against HIV-1 reverse transcriptase. J. Med. Chem. 42, 859-867). Of the sugar-modified cytosine nucleosides, some N<sup>4</sup>-acyl and imine-substituted 2',3'-dideoxy-3'-C-hydroxymethylcytidine analogues have been synthesized (Mauldin *et al.* (1998) Synthesis and antiviral activity of prodrugs of the nucleoside 1-[2',3'-dideoxy-3'-C-(hydroxymethyl)-β-D-erythropentofuranosyl] cytosine. Bioorg. Med. Chem. 6, 577-585), and some N<sup>4</sup>-acetyl- and phosphonoacetyl-2',3'-dideoxy-3'-thiacytidine nucleosides have been prepared (Charvet *et al.* (1993) Inhibition of human immunodeficiency virus type 1 replication by phosphonoformate- and phosphonoacetate-2',3'-dideoxy-3'-thiacytidine conjugates. J. Med. Chem. 37, 2216-2223).

Therefore, it is an object of the present invention to provide a method and composition for the treatment or prevention of HIV infection in human patients.

It is another object of the present invention to provide a method and composition for the treatment or prevention of HBV infection in human patients or other host animals.

It is still another object of the present invention to provide a method and composition for the treatment or prevention of HIV and HBV infection in human patients or other host animals.

## II. Stereoisomerism and Polymorphism

The compounds of the present invention have asymmetric centers and occur as racemates, racemic mixtures, individual diastereomers or enantiomers, with all isomeric forms being included in the present invention. Some compounds may exhibit polymorphism. The present invention encompasses racemic, optically-active, polymorphic, or stereoisomeric form, or mixtures thereof, of a compound of the invention, which possess the useful properties described herein. The optically active forms can be prepared by, for example, resolution of the racemic form by recrystallization techniques, by synthesis from optically-active starting materials, by chiral synthesis, or by chromatographic separation using a chiral stationary phase or by enzymatic resolution.

Examples of methods to obtain optically active materials include at least the following.

- i) physical separation of crystals: a technique whereby macroscopic crystals of the individual enantiomers are manually separated. This technique can be used if crystals of the separate enantiomers exist, *i.e.*, the material is a conglomerate, and the crystals are visually distinct;
- ii) simultaneous crystallization: a technique whereby the individual enantiomers are separately crystallized from a solution of the racemate, possible only if the latter is a conglomerate in the solid state;
- iii) enzymatic resolutions: a technique whereby partial or complete separation of a racemate by virtue of differing rates of reaction for the enantiomers with an enzyme;
- iv) enzymatic asymmetric synthesis: a synthetic technique whereby at least one step of the synthesis uses an enzymatic reaction to obtain an enantiomerically pure or enriched synthetic precursor of the desired enantiomer;
- v) chemical asymmetric synthesis: a synthetic technique whereby the desired enantiomer is synthesized from an achiral precursor under

conditions that produce asymmetry (*i.e.*, chirality) in the product, which may be achieved using chiral catalysts or chiral auxiliaries;

5           vi)    diastereomer separations: a technique whereby a racemic compound is reacted with an enantiomerically pure reagent (the chiral auxiliary) that converts the individual enantiomers to diastereomers. The resulting diastereomers are then separated by chromatography or crystallization by virtue of their now more distinct structural differences and the chiral auxiliary later removed to obtain the desired enantiomer;

10           vii) first- and second-order asymmetric transformations: a technique whereby diastereomers from the racemate equilibrate to yield a preponderance in solution of the diastereomer from the desired enantiomer or where preferential crystallization of the diastereomer from the desired enantiomer perturbs the equilibrium such that  
15           eventually in principle all the material is converted to the crystalline diastereomer from the desired enantiomer. The desired enantiomer is then released from the diastereomer;

20           viii) kinetic resolutions: this technique refers to the achievement of partial or complete resolution of a racemate (or of a further resolution of a partially resolved compound) by virtue of unequal reaction rates of the enantiomers with a chiral, non-racemic reagent or catalyst under kinetic conditions;

25           ix)    enantiospecific synthesis from non-racemic precursors: a synthetic technique whereby the desired enantiomer is obtained from non-chiral starting materials and where the stereochemical integrity is not or is only minimally compromised over the course of the synthesis;

30           x)    chiral liquid chromatography: a technique whereby the enantiomers of a racemate are separated in a liquid mobile phase by virtue of their differing interactions with a stationary phase (including but not limited to via chiral HPLC). The stationary phase can be made of

chiral material or the mobile phase can contain an additional chiral material to provoke the differing interactions;

- 5 xi) chiral gas chromatography: a technique whereby the racemate is volatilized and enantiomers are separated by virtue of their differing interactions in the gaseous mobile phase with a column containing a fixed non-racemic chiral adsorbent phase;
- xii) extraction with chiral solvents: a technique whereby the enantiomers are separated by virtue of preferential dissolution of one enantiomer into a particular chiral solvent;
- 10 xiii) transport across chiral membranes: a technique whereby a racemate is placed in contact with a thin membrane barrier. The barrier typically separates two miscible fluids, one containing the racemate, and a driving force such as concentration or pressure differential causes preferential transport across the membrane barrier.
- 15 Separation occurs as a result of the non-racemic chiral nature of the membrane that allows only one enantiomer of the racemate to pass through.

Chiral chromatography, including but not limited to simulated moving bed chromatography, is used in one embodiment. A wide variety of chiral stationary phases are commercially available.

### III. Definitions

The term “independently” is used herein to indicate that the variable, which is independently applied, varies independently from application to application. Thus, in a compound such as R”XYR”, wherein R” is “independently carbon or nitrogen,” both R” can be carbon, both R” can be nitrogen, or one R” can be carbon and the other R” nitrogen.

25

As used herein, the term “substantially free of” or “substantially in the absence of” refers to a nucleoside composition that includes at least 95% to 98 % by weight, and even more preferably 99% to 100% by weight, of the designated enantiomer of that nucleoside.

In a preferred embodiment, in the methods and compounds of this invention, the compounds are substantially free of enantiomers.

Similarly, the term "isolated" refers to a nucleoside composition that includes at least 85 or 90% by weight, preferably 95% to 98 % by weight, and even more preferably 99% to 100% by weight, of the nucleoside, the remainder comprising other chemical species or enantiomers.

The term "alkyl," as used herein, unless otherwise specified, refers to a saturated straight, branched, or cyclic, primary, secondary, or tertiary hydrocarbon. The term includes both substituted and unsubstituted alkyl groups. The alkyl group may be optionally substituted with any moiety that does not otherwise interfere with the reaction or that provides an improvement in the process, including but not limited to but limited to halo, haloalkyl, hydroxyl, carboxyl, acyl, aryl, acyloxy, amino, amido, carboxyl derivatives, alkylamino, dialkylamino, arylamino, alkoxy, aryloxy, nitro, cyano, sulfonic acid, thiol, imine, sulfonyl, sulfanyl, sulfinyl, sulfamonyl, ester, carboxylic acid, amide, phosphonyl, phosphinyl, phosphoryl, phosphine, thioester, thioether, acid halide, anhydride, oxime, hydrozine, carbamate, phosphonic acid, phosphonate, either unprotected, or protected as necessary, as known to those skilled in the art, for example, as taught in Greene *et al.*, Protective Groups in Organic Synthesis, John Wiley & Sons, Second Edition, 1991, hereby incorporated by reference. Specifically included are CF<sub>3</sub> and CH<sub>2</sub>CF<sub>3</sub>

In the text, whenever the term C(alkyl range) is used, the term independently includes each member of that class as if specifically and separately set out. As a nonlimiting example, the term "C<sub>1-22</sub>" independently represents each species that falls within the scope. The term "host," as used herein, refers to a unicellular or multicellular organism in which the virus can replicate, including but not limited to cell lines and animals, and preferably a human. Alternatively, the host can be carrying a part of the viral genome, whose replication or function can be altered by the compounds of the present invention. The term host specifically refers to infected cells, cells transfected with all or part of the viral genome and animals, in particular, primates (including but not limited to chimpanzees) and humans. In most animal applications of the present invention, the host is a human patient. Veterinary applications, in certain indications, however, are clearly anticipated by the present invention (such as chimpanzees).

The term “pharmaceutically acceptable salt or prodrug” is used throughout the specification to describe any pharmaceutically acceptable form (such as an ester, phosphate ester, salt of an ester or a related group) of a nucleoside compound which, upon administration to a patient, provides the nucleoside compound. Pharmaceutically acceptable salts include those derived from pharmaceutically acceptable inorganic or organic bases and acids. Suitable salts include those derived from alkali metals such as potassium and sodium, alkaline earth metals such as calcium and magnesium, among numerous other acids well known in the pharmaceutical art. Pharmaceutically acceptable prodrugs refer to a compound that is metabolized, for example hydrolyzed or oxidized, in the host to form the compound of the present invention. Typical examples of prodrugs include compounds that have biologically labile protecting groups on a functional moiety of the active compound. Prodrugs include compounds that can be oxidized, reduced, aminated, deaminated, hydroxylated, dehydroxylated, hydrolyzed, dehydrolyzed, alkylated, dealkylated, acylated, deacylated, phosphorylated, dephosphorylated to produce the active compound. The compounds of this invention possess antiviral activity against *Flaviviridae*, or are metabolized to a compound that exhibits such activity.

Prodrugs also include natural or unnatural amino acid esters of the disclosed nucleosides (*see, e.g.*, European Patent Specification No. 99493, the text of which is incorporated by reference, which describes amino acid esters of acyclovir, specifically the glycine and alanine esters which show improved water-solubility compared with acyclovir itself, and US Pat. No. 4,957,924 (Beauchamp), which discloses the valine ester of acyclovir, characterized by side-chain branching adjacent to the  $\alpha$ -carbon atom, which showed improved bioavailability after oral administration compared with the alanine and glycine esters). A process for preparing such amino acid esters is disclosed in US Pat. No. 4,957,924 (Beauchamp), the text of which is incorporated by reference. As an alternative to the use of valine itself, a functional equivalent of the amino acid may be used (*e.g.*, an acid halide such as the acid chloride, or an acid anhydride). In such a case, to avoid undesirable side-reactions, it may be advantageous to use an amino-protected derivative.

#### IV. Nucleotide Salt or Prodrug Formulations

In cases where compounds are sufficiently basic or acidic to form stable nontoxic acid or base salts, administration of the compound as a pharmaceutically acceptable salt may be appropriate. Examples of pharmaceutically acceptable salts are organic acid addition salts formed with acids, which form a physiological acceptable anion, for example, tosylate, methanesulfonate, acetate, citrate, malonate, tartarate, succinate, benzoate, ascorbate,  $\alpha$ -ketoglutarate and  $\alpha$ -glycerophosphate. Suitable inorganic salts may also be formed, including but not limited to, sulfate, nitrate, bicarbonate and carbonate salts.

Pharmaceutically acceptable salts may be obtained using standard procedures well known in the art, for example by reacting a sufficiently basic compound such as an amine with a suitable acid, affording a physiologically acceptable anion. Alkali metal (*e.g.*, sodium, potassium or lithium) or alkaline earth metal (*e.g.*, calcium) salts of carboxylic acids can also be made.

Any of the nucleosides described herein can be administered as a nucleotide prodrug to increase the activity, bioavailability, stability or otherwise alter the properties of the nucleoside. A number of nucleotide prodrug ligands are known. In general, alkylation, acylation or other lipophilic modification of the mono, di or triphosphate of the nucleoside will increase the stability of the nucleotide. Examples of substituent groups that can replace one or more hydrogens on the phosphate moiety are alkyl, aryl, steroids, carbohydrates, including but not limited to sugars, 1,2-diacylglycerol and alcohols. Many are described in R. Jones & N. Bischofberger, *Antiviral Research*, **27** (1995) 1-17. Any of these can be used in combination with the disclosed nucleosides to achieve a desired effect.

The active nucleoside can also be provided as a 5'-phosphoether lipid or a 5'-ether lipid, as disclosed in the following references, which are incorporated by reference: Kucera, L.S., N. Iyer, E. Leake, A. Raben, Modest E.K., D.L.W., and C. Piantadosi, "Novel membrane-interactive ether lipid analogs that inhibit infectious HIV-1 production and induce defective virus formation," *AIDS Res. ## V. Combination or Alternation Therapy

In another embodiment for the treatment of HIV or HBV infection, the active compound or its prodrug or salt can be administered in combination or alternation with another antiviral agent, such as another active anti-HIV or anti-HBV agent, including but not limited to those of the formulae above, others listed below or known in the art. In general, in combination therapy, effective dosages of two or more agents are administered together, whereas during alternation therapy, an effective dosage of each agent is administered serially. The dosage will depend on absorption, inactivation and excretion rates of the drug as well as other factors known to those of skill in the art. It is to be noted that dosage values will also vary with the severity of the condition to be alleviated. It is to

be further understood that for any particular subject, specific dosage regimens and schedules should be adjusted over time according to the individual need and the professional judgment of the person administering or supervising the administration of the compositions.

## **VI. Pharmaceutical Compositions**

Host, including but not limited to humans, infected with a human immunodeficiency virus, a hepatitis virus, or a gene fragment thereof, can be treated by  
15           administering to the patient an effective amount of the active compound or a pharmaceutically acceptable prodrug or salt thereof in the presence of a pharmaceutically acceptable carrier or diluent. The active materials can be administered by any appropriate route, for example, orally, parenterally, intravenously, intradermally, subcutaneously, or topically, in liquid or solid form.

20           A preferred dose of the compound for an HIV or HBV infection will be in the range from about 1 to 50 mg/kg, preferably 1 to 20 mg/kg, of body weight per day, more generally 0.1 to about 100 mg per kilogram body weight of the recipient per day. The effective dosage range of the pharmaceutically acceptable salts and prodrugs can be calculated based on the weight of the parent nucleoside to be delivered. If the salt or  
25           prodrug exhibits activity in itself, the effective dosage can be estimated as above using the weight of the salt or prodrug, or by other means known to those skilled in the art.

The compound is conveniently administered in unit any suitable dosage form, including but not limited to but not limited to one containing 7 to 3000 mg, preferably 70

to 1400 mg of active ingredient per unit dosage form. An oral dosage of 50-1000 mg is usually convenient.

Ideally the active ingredient should be administered to achieve peak plasma concentrations of the active compound of from about 0.2 to 70  $\mu\text{M}$ , preferably about 1.0 to 10  $\mu\text{M}$ . This may be achieved, for example, by the intravenous injection of a 0.1 to 5% solution of the active ingredient, optionally in saline, or administered as a bolus of the active ingredient.

The concentration of active compound in the drug composition will depend on absorption, inactivation and excretion rates of the drug as well as other factors known to those of skill in the art. It is to be noted that dosage values will also vary with the severity of the condition to be alleviated. It is to be further understood that for any particular subject, specific dosage regimens should be adjusted over time according to the individual need and the professional judgment of the person administering or supervising the administration of the compositions, and that the concentration ranges set forth herein are exemplary only and are not intended to limit the scope or practice of the claimed composition. The active ingredient may be administered at once, or may be divided into a number of smaller doses to be administered at varying intervals of time.

A preferred mode of administration of the active compound is oral. Oral compositions will generally include an inert diluent or an edible carrier. They may be enclosed in gelatin capsules or compressed into tablets. For the purpose of oral therapeutic administration, the active compound can be incorporated with excipients and used in the form of tablets, troches or capsules. Pharmaceutically compatible binding agents, and/or adjuvant materials can be included as part of the composition.

The tablets, pills, capsules, troches and the like can contain any of the following ingredients, or compounds of a similar nature: a binder such as microcrystalline cellulose, gum tragacanth or gelatin; an excipient such as starch or lactose, a disintegrating agent such as alginic acid, Primogel or corn starch; a lubricant such as magnesium stearate or Sterotes; a glidant such as colloidal silicon dioxide; a sweetening agent such as sucrose or saccharin; or a flavoring agent such as peppermint, methyl salicylate, or orange flavoring. When the dosage unit form is a capsule, it can contain, in addition to material of the above type, a liquid carrier such as a fatty oil. In addition, unit dosage forms can contain various

other materials that modify the physical form of the dosage unit, for example, coatings of sugar, shellac, or other enteric agents.

The compound can be administered as a component of an elixir, suspension, syrup, wafer, chewing gum or the like. A syrup may contain, in addition to the active compound(s), sucrose as a sweetening agent and certain preservatives, dyes and colorings and flavors.

The compound or a pharmaceutically acceptable prodrug or salts thereof can also be mixed with other active materials that do not impair the desired action, or with materials that supplement the desired action, such as antibiotics, antifungals, anti-inflammatories or other antivirals, including but not limited to other nucleoside compounds. Solutions or suspensions used for parenteral, intradermal, subcutaneous, or topical application can include the following components: a sterile diluent such as water for injection, saline solution, fixed oils, polyethylene glycols, glycerine, propylene glycol or other synthetic solvents; antibacterial agents such as benzyl alcohol or methyl parabens; antioxidants such as ascorbic acid or sodium bisulfite; chelating agents, such as ethylenediaminetetraacetic acid; buffers, such as acetates, citrates or phosphates, and agents for the adjustment of tonicity, such as sodium chloride or dextrose. The parental preparation can be enclosed in ampoules, disposable syringes or multiple dose vials made of glass or plastic.

If administered intravenously, preferred carriers are physiological saline or phosphate buffered saline (PBS).

In a preferred embodiment, the active compounds are prepared with carriers that will protect the compound against rapid elimination from the body, such as a controlled release formulation, including but not limited to implants and microencapsulated delivery systems. Biodegradable, biocompatible polymers can be used, such as ethylene vinyl acetate, polyanhydrides, polyglycolic acid, collagen, polyorthoesters and polylactic acid. For example, enterically coated compounds can be used to protect cleavage by stomach acid. Methods for preparation of such formulations will be apparent to those skilled in the art. Suitable materials can also be obtained commercially.

Liposomal suspensions (including but not limited to liposomes targeted to infected cells with monoclonal antibodies to viral antigens) are also preferred as pharmaceutically acceptable carriers. These may be prepared according to methods known to those skilled

in the art, for example, as described in US Pat. No. 4,522,811 (incorporated by reference). For example, liposome formulations may be prepared by dissolving appropriate lipid(s) (such as stearyl phosphatidyl ethanolamine, stearyl phosphatidyl choline, arachadyl phosphatidyl choline, and cholesterol) in an inorganic solvent that is then evaporated, leaving behind a thin film of dried lipid on the surface of the container. An aqueous solution of the active compound or its monophosphate, diphosphate, and/or triphosphate derivatives is then introduced into the container. The container is then swirled by hand to free lipid material from the sides of the container and to disperse lipid aggregates, thereby forming the liposomal suspension.

## VII. Processes for the Preparation of Active Compounds

A method for the facile preparation of N<sup>4</sup>-acyl-substituted 2',3'-dideoxy-5-fluorocytidine and 2',3'-didehydro-2',3'-dideoxy-5-fluorocytidine nucleosides is also provided. The method includes condensation of a 5'-O-silyl protected 2',3'-dideoxy-5-fluorocytidine or a 5'-O-silyl protected 2',3'-didehydro-2',3'-dideoxy-5-fluorocytidine, with either a carboxylic acid chloride, or carboxylic acid anhydride, or a carboxylic acid, followed by desilylation. The other N<sup>4</sup>-acyl-substituted cytosine nucleosides can be synthesized using the similar approaches.

The N<sup>4</sup>-acyl-substituted 2',3'-dideoxy-5-fluorocytidine and 2',3'-didehydro-2',3'-dideoxy-5-fluorocytidine nucleosides disclosed herein can be prepared as described in detail below, or by other assays known to those skilled in the art.

The present invention is further illustrated in the following examples. It will be understood by one of ordinary skill in the art that these examples are in no way limiting and that variations of detail can be made without departing from the spirit and scope of the present invention.

## EXAMPLES

Anhydrous solvents were purchased from Aldrich Chemical Company, Inc. (Milwaukee). Melting points (mp) were determined on an Electrothermal digit melting

point apparatus and are uncorrected.  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra were taken on a Varian Unity Plus 400 spectrometer at room temperature and reported in ppm downfield from internal tetramethylsilane. Deuterium exchange, decoupling experiments or 2D-COSY were performed to confirm proton assignments. Signal multiplicities are represented by s (singlet), d (doublet), dd (doublet of doublets), t (triplet), q (quadruplet), br (broad), bs (broad singlet), m (multiplet). All J-values are in Hz. Mass spectra were recorded on a JEOL JMS-SX/SX102A/E mass spectrometer. Elemental analyses were performed by Atlantic Microlab Inc. (Norcross, GA). Analytic TLC was performed on Whatman LK6F silica gel plates, and preparative TLC on Whatman PK5F silica gel plates. Column chromatography was carried out on Silica Gel (Fisher, S733-1) at atmospheric pressure.

The reaction was quenched by addition of anhydrous MeOH (10 mL), and the mixture was allowed to warm to room temperature. After stirring at room temperature for 30 min, EtOAc (50 mL) and water (50 mL) were added. The resulting white precipitate was filtered, and the aqueous layer was extracted with EtOAc. The combined organic phase was washed with water and brine, dried (Na<sub>2</sub>SO<sub>4</sub>), filtered, and evaporated. To the residue was added a solution of **6** (5.53 g, 10.0 mmol) in anhydrous 1,2-dichloroethane (25 mL), and the mixture was cooled to 5°C. TMSOTf (2.0 mL, 11 mmol) was added, and the resulting solution was stirred at 5°C for 15 min under an argon atmosphere, then at room temperature for another 30 min. ### Example 13

#### *Anti-HIV (in PBM cells) Assay*

Anti-HIV-1 activity of the compounds was determined in human peripheral blood mononuclear (PBM) cells as described previously (Schinazi R.F., McMillan A., Cannon D., Mathis R., Lloyd R.M. Jr., Peck A., Sommadossi J.-P., St. Clair M., Wilson J., Furman P.A., Painter G., Choi W.-B., Liotta D.C. *Antimicrob. Agents Chemother.* **1992**, 36, 2423; Schinazi R.F., Sommadossi J.-P., Saalman V., Cannon D., Xie M.-Y., Hart G., Smith G., Hahn E. *Antimicrob. Agents Chemother.* **1990**, 34, 1061). Stock solutions (20-40 mM) of the compounds were prepared in sterile DMSO and then diluted to the desired concentration in growth medium. Cells were infected with the prototype HIV-1<sub>LAI</sub> at a multiplicity of infection of 0.01. Virus obtained from the cell supernatant was quantified on day 6 after infection by a reverse transcriptase assay using (rA)<sub>n</sub>•(dT)<sub>12-18</sub> as template-primer. The DMSO present in the diluted solution (< 0.1%) had no effect on the virus yield. AZT was included as positive control. The antiviral EC<sub>50</sub> and EC<sub>90</sub> were obtained from the concentration-response curve using the median effective method described previously (Chou T.-C. & Talalay P. *Adv. Enzyme Regul.* **1984**, 22, 27-55; Belen'kii M.S. & Schinazi R.F. *Antiviral Res.* **1994**, 25, 1-11).

#### *Anti-HIV (in MT-2 cells) Assay*

In a second antiviral testing system, the potency of the compounds was determined by measurement of viral RNA accumulation in HIV-1<sub>RF</sub> infected MT-2 cells (Bachelier LT, Paul M, Otto MJ, Jadhav PK, Stone BA & Miller JA (1994) An assay for HIV RNIn

infected cell lysates, and its use for rapid evaluation of antiviral efficacy. *Antivir. Chem. Chemother.* 5:111-121). The virus titer was established to determine the dilution producing 15 to 30 ng/RNA per well of HIV RNIn 3 days of infection. HIV-1 RNA was quantified using biotinylated capture and alkaline phosphatase-derivatized reporter oligonucleotides as described previously (Charvet A-S, Camplo M, Faury P, Graciet JC, Mourier N, Chermann JC & Kraus JL (1994) Inhibition of human immunodeficiency virus type 1 replication by phosphonoformate- and phosphonoacetate-2',3'-dideoxy-3'-thiacytidine conjugates. *J. Med. Chem.* 37:2216-2223). In a third system, the effect of analogs on the replication of HIV-1<sub>NL4-3</sub> was determined via the InterCompany Consortium consensus p24 assay as previously described (Jadhav PK & MacKay MF (1997) Cyclic urea amide: HIV-1 protease inhibitors with low nanomolar potency against both wild types and protease inhibitor resistant mutants of HIV. *J. Med. Chem.* 40:181-190). Recombinant viruses were recovered by transfecting the appropriate NL4-3 plasmid by lipofection. Virus stocks recovered 7 to 10 days post-transfection were titrated on MT-4 cells to determine if the dilution produced 1,000 to 3,000 ng p24 in 4 days. This dilution was then used in drug susceptibility assays, where drug was added 24 h post infection of cells, and p24 quantified by ELISA 3 days later.

#### Example 14

##### *Anti-HBV assay*

The anti-HBV activity of the compounds was determined by treating the AD-38 cell line carrying wild type HBV under the control of tetracycline (Ladner S.K., Otto M.J., Barker C.S., Zaifert K., Wang G.H., Guo J.T., Seeger C. & King R.W. *Antimicrob. Agents Chemother.* 1997, 41, 1715-1720). Removal of tetracycline from the medium [Tet (-)] results in the production of HBV. The levels of HBV in the culture supernatant fluids from cells treated with the compounds were compared with that of the untreated controls. Control cultures with tetracycline [Tet (+)] were also maintained to determine the basal levels of HBV expression. 3TC was included as positive control (see **Tables 1, 2**).

**Example 15***Cytotoxicity assay*

The toxicity of the compounds was assessed in Vero, human PBM, CEM (human lymphoblastoid), MT-2, and HepG2 cells, as described previously (Schinazi R.F., Sommadossi J.-P., Saalman V., Cannon D.L., Xie M.-Y., Hart G.C., Smith G.A. & Hahn E.F. *Antimicrob Agents Chemother.* **1990**, *34*, 1061-1067). Cycloheximide was included as positive cytotoxic control, and untreated cells exposed to solvent were included as negative controls. The cytotoxicity IC<sub>50</sub> was obtained from the concentration-response curve using the median effective method described previously (Chou T.-C. & Talalay P. *Adv. Enzyme Regul.* **1984**, *22*, 27-55; Belen'kii M.S. & Schinazi R.F. *Antiviral Res.* **1994**, *25*, 1-11) (see **Tables 1, 2**).
